

WHAT I LEARNED

As part of this project, I created a command-line version of Student Grade Tracker in Python. I utilized classes, inheritance, methods, lists, dictionaries, loops, conditionals, and input validation. I created a parent class of Assignment and implemented Homework and Exam as its subclasses connecting tracker's functionality to the separate main menu.

Challenges I faced

The main issues were ensuring the correct functioning of two Python files that had identical class and method names, implementing input validation for user's data and ensuring that no program crashes occurred due to that, formatting the date correctly, and avoiding the creation of duplicate assignments. In addition, I dealt with the assignment listing, filtering, and grade summary calculation issues. This process helped me see the importance of even the slightest error in names or logic as far as it can cause the malfunctioning of the whole program.

If given more time

This project enhanced my understanding of object-oriented programming and the way Python's components work together. I also learned the necessity to test the program not only with normal but also with extreme inputs. If I continued working on this project, I would improve the naming and filtering.
